Abstract - Breast cancer usually begins from the breast tissue and progresses rapidly. The disease is the most common cancer that women suffer from. With a late diagnosis of breast cancer, the likelihood of the relapse of the disease is increased. The earlier breast cancer is diagnosed, the greater the likelihood of successful treatment would be. Also, if cancer is diagnosed in the early stages, the likelihood of the relapse of cancerous tumours is decreased. The presence of various symptoms and features of this disease makes it difficult for doctors to diagnose. The neural network provides the possibility of analyzing patients' clinical data for medical decision making. The purpose of this paper is to provide a model for increasing the accuracy of the prediction of breast cancer.

In this study, patients' information has been collected from the standard database of Mortaz Super Specialty Hospital of Yazd. The medical records of 574 patients with breast cancer having a total of 32 features have been investigated. Each patient has been followed for at least one year. In order to provide a model of prediction of breast cancer, particle swarm optimization algorithm and MLP neural network are used.

The proposed model was compared with the methods of the nearest neighbour, Naive Bayes and decision tree. The results show that the prediction accuracy of the proposed model is equal to 0.966. Also, for the methods of Naive Bayes, decision tree, and the nearest neighbour, prediction accuracy is 0.91, 0.929 and 0.913, respectively.

In predicting breast cancer, the proposed model includes a minimum error rate and maximum accuracy and validity compared to other models. The naive Bayes method has a maximum error rate and minimum accuracy.

Keywords - Breast Cancer, Particle Swarm Optimization Algorithm, MLP Neural Network, Increasing the prediction accuracy.

I. INTRODUCTION

Breast cancer is preventable and early diagnosable, and by providing specific strategies, it is possible to reduce the late referral of the patient. Effective treatment of breast cancer is important in order to increase survival, reduce death and improve quality of life. This disease is a major threat to the health of women and is considered as one of the most common causes in reducing the lives of women [1], [4]. Breast cancer is due to the excessive growth of abnormal cells in the breast [5], [6]. To predict, diagnose and treat the disease, many factors are applied, such as the presence of a mass, lymph nodes involvement, nipple niche, breast discharge, etc. [7], [8]. The large similarity in clinical and laboratory symptoms of breast cancer increases the risk of false diagnosis [9]. The mass is the most common symptom of breast cancer that often is detected accidentally by the patient herself, and in other cases, it is diagnosed by a physician in physical checkups [1], [2]. This mass may be painful, but in most cases, it is painless. In some cases, breast cancer occurs in multiple masses [10], [13].

The similarity of clinical and laboratory symptoms of breast cancer increases the likelihood of an error in diagnosis. Diagnosis and prediction of various diseases are possible by the neural network. Discovering useful patterns between disease and clinical and laboratory symptoms of a patient is one of the uses of neural network applications in medicine. A useful model is a model in data that describes the relationship between a subset of a patient's data and the disease diagnosis [14].

In recent years, with the advances in early diagnosis of the disease, its treatment has been more successful. If breast masses are detected in small sizes, they can be well treated. A neural network is a new method for the early diagnosis of breast cancer. Sheikhpour et al. introduced the diagnosis of breast cancer using two-step reduction of the extracted properties of needle aspiration and data analysis algorithms [15]. The use of three data analysis methods for diagnosis of breast

cancer was introduced by Delone et al. that they were simulated the prediction of cancer by decision tree (C5) with an accuracy of 93.6%, artificial neural network with an accuracy of 91.2% and logistic regression model with an accuracy of 89.2% [16]. Aruna et al. predicted breast cancer through the WDBC database by data analysis models such as decision tree and Naive Bayes and neural network with an accuracy of 92.97%, 92.61% and 67/93, respectively [17]. Ester et al. provided a discrete linear analysis in the diagnosis of breast cancer using a WDBC database with an accuracy of 96.8% [18].

The accuracy of neural network’s diagnosis and prediction can be increased by setting the parameters of the network using collective intelligence algorithms. Collective intelligence is actually formed on the basis of the simulation of the collective behaviour of a group of animals like birds and fishes [19].In this study, it was introduced a model for increasing the accuracy of MLP neural network’s diagnosis and prediction based on the particle swarm optimization algorithm by designing a questionnaire completing and collecting data sets related to patients’ records in Mortaz super speciality hospital, Yazd.

II. METHODOLOGY

A. Data Sets Collection

To prepare the data collection related to breast cancer, first, a standard questionnaire was designed on the basis of new features and then completed and collected in Mortaz super speciality hospital, Yazd. The data are related to 2014 to 2015. The data set includes 574 samples, of which 17 samples lack complete information. The samples lacking complete information were estimated by the maximum frequency method. For each patient, 32 features are registered. The initial values interval of the patient’s clinical features is shown in table 1. The class names and the number of available samples in each class are shown in table 2. The appropriate data format as the input of data analysis is effective in results and output. If the values of the dataset's features are in a different domain, the likelihood of an error in the findings will be increased. Normalization is said to put the data of a statistical population in the same domain [20]. In the proposed model, the normalization method is Max / Min and in the interval of [1-0] [21].

B. MLP Neural Network

The variety of neural networks is quite wide, especially in medicine, is used by the learning process to predict diseases. The method identifies the relationships and patterns between data through processors called neurons [22],[23], [24]. The neural network approach provides a mapping between the input space (input layer) and the optimal space (output layer). The input layer receives the data and delivers it to the hidden layers. Information is processed in hidden layers and delivered to the output layer. Each network is trained by receiving some examples. Learning is done through the training process. Network learning is performed when the difference between the predicted values and the actual

information is acceptable. The trained neural network is used for prediction with a new set of data [25]. The main features of the artificial neural network include the ability to learn patterns, high processing speed, the ability to generalize knowledge after learning, flexibility to deal with unwanted errors, and not to cause a significant disturbance if there is an error [26].

C. Particle Swarm Optimization Algorithm

Particle swarm optimization algorithm or PSO uses social behaviour of bird or fish groups during food search to guide the population to the promising area in the search space [27], [28]. In PSO, each answer to a problem is the position of a bird in the search space that is called a particle. All particles include a value of merit obtained by the fitness function, which is the purpose of optimization. Moreover, each particle also has a component called the velocity that determines its path in the search space. The PSO population contains all the particles called the Swarm. The PSO algorithm includes the two models of velocity and location equations. The coordinates of each particle represent a possible answer associated with two vectors. The vectors of position () and the velocity () are the two dependent vectors and related to each i particle in the N-dimensional search space, which are respectively expressed as follows.

$$x_i^{k+1} = x_i^k + Cv_i^{k+1}$$

$$v_i = [v_{i1}, v_{i2}, \dots, v_{iN}]$$

$$x_i = [x_{i1}, x_{i2}, \dots, x_{iN}]$$

A community of birds consists of a number of particles (possible responses) flying in an appropriate response space to search for optimal solutions. The position of each particle is updated on the basis of the best of its search, the best overall experience of group flight and the vector of the previous particle velocity, and based on the following equations.

$$x_i^{k+1} = x_i^k + Cv_i^{k+1}$$

$$v_i^{k+1} = wv_i^k + c_1r_1(PBest_i^k - x_i^k) + c_2r_2(GBest_i^k - x_i^k)$$

In which c1 and c2 are two positive integer constants, r1 and r2 are two random numbers with uniform distribution in the range [0, 1] and w is the inertia weight which is chosen as follows.

$$w = w_{\max} - \frac{w_{\max} - w_{\min}}{iter_{\max}} * iter$$

Which $iter_{\max}$ is the maximum number of repeats, and iteration is the number of current repeats. $PBest_i^k$ Is the best position of the particle, which is obtained on the basis of the particle's experience, is

$$PBest_i^k = [x_{i1}^{pbest}, x_{i2}^{pbest}, \dots, x_{iN}^{pbest}]$$

$GBest_i^k$ Is the best position of the particle-based on the general group experience (3) and consists of:

$$GBest = [x_1^{gbest}, x_2^{gbest}, \dots, x_N^{gbest}]$$

And K is the repeat index.

Table 1. Names And Number Of Class Samples

| Samples number | Class name |
|----------------|------------|
| 183 | Healthy |
| 329 | Benin g |
| 62 | Malignant |

D. The Proposed Model

In this paper, MLP (Multilayer perception) network is used to predict breast cancer. This network contains an input layer, one or more hidden layers and an output layer. The available datasets in the files of patients with breast cancer are sent to the input layer for processing. To train the network, the backpropagation algorithm (BP) is usually used. During the training of the MLP network using the BP learning algorithm, the computation is first performed from the network’s input to the network’s output, and then the calculated error values are released to the previous layers. Initially, the output is calculated layer by layer, and the output of each layer is the input of the next layer. In backpropagation mode, the output layers are firstly modulated since there is a desirable amount for each neuron of the output layer, and it is possible to modulate the weights by their help and updating rules.

All features and findings are of particular importance in the diagnosis and prediction of breast cancer. In other words, all features do not have the same value. For example, in the diagnosis of the disease, two features of the BMI and the presence of a tumour include different significance. It is important to know the value of each feature and how much it plays a role in diagnosing the disease. In the study, the value and role of each feature are specified by the neural network, and the disease is diagnosed. The training stages of the neural network of the proposed algorithm are:

- Step One: Each matrix input value is assigned a random weight.
- Step Two: The appropriate input and output vector is selected.
- Step Three: The output of a neuron in each layer, and so, the output of neurons in the output layer is computed.
- Step Four: Weights are updated to the previous layers by the method of network error propagation.

- Step Five: The function of the trained network is evaluated.

After training, the neural network will be able to accurately predict the noise levels. The overall structure of the used neural network is shown in Fig 1. and Fig 2 shows the trend of the proposed approach.

Fig. 1 The Structure of Artificial Neural Network

The weakness in the results of the MLP neural network may be due to the long or uncertain learning time, the inability to properly select the learning coefficients and the inappropriate distribution of the primary weights. One of the factors of disruption in neural network’s learning is inappropriate values of parameters. In this paper, the PSO algorithm is used to set parameters for learning the network. The target function for the PSO algorithm is defined as shown in fig 2. In the proposed algorithm, the number of hidden layers and the number of hidden neurons in each layer are considered as particles. Assuming:

m= the number of hidden layers

n= the number of hidden neurons in each layer

The values of n, m must be closer to the values. The proposed algorithm is obtained when the values of n, m make our desired criteria achieve their optimum levels. In this case, the updated n, m that makes our intended criteria are optimal is considered as n, m. Also, the best global is obtained when the values of n, m are equal to the values.

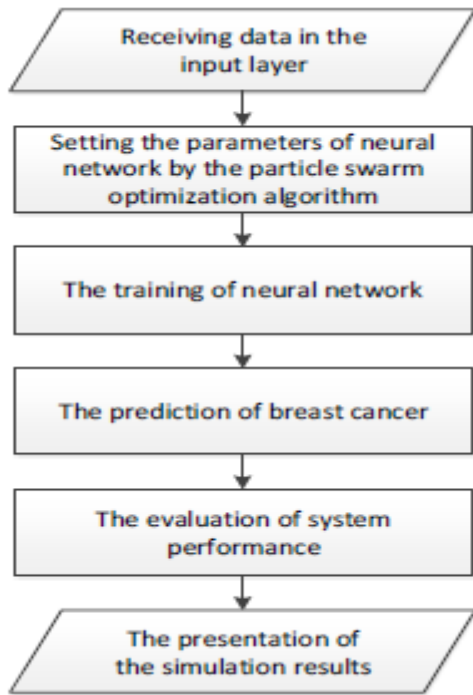

Fig. 2 The Trend of the Proposed Approach

By placing and in $PBest_i^k$ an equation, the particle velocity is calculated. Then, by placing the particle's velocity in $GBest_i^k$ an equation, the particle position can be calculated. The following relationships are used to calculate the next position of each particle.

$$m^{k+1} = m^k + v_m^{k+1}$$

$$n^{k+1} = n^k + v_n^{k+1}$$

The obtained $n_i + 1$ and $m_i + 1$ from above are new particles, and they are placed in the position of the available n, m in the preceding stage. Thus, the values of n, m, defined in the MLP neural network as static, are converted into dynamic variables in the PSO algorithm and changed depending on the network conditions. The methodology and the chart of the PSO algorithm's workflow for calculating optimal m and n are shown in Fig 3.

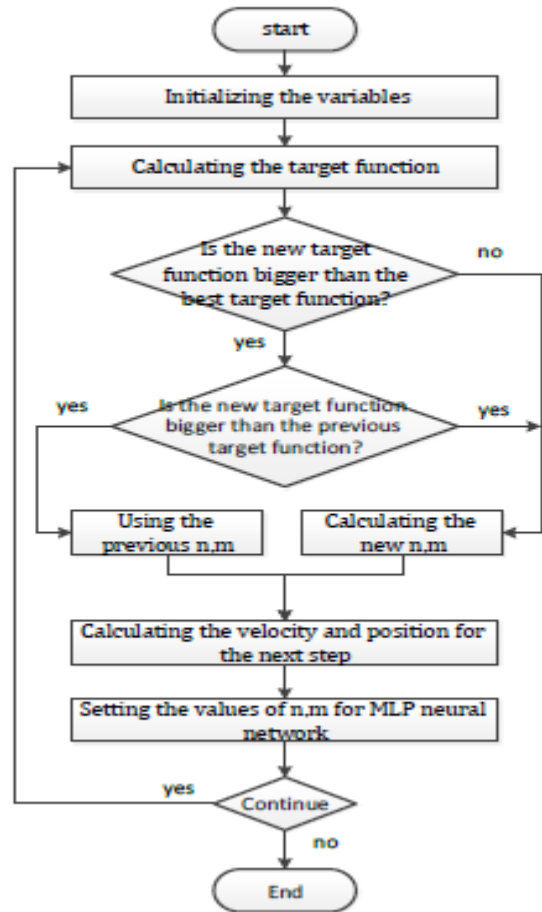

Fig. 3 The chart of the methodology of PSO algorithm and optimal m and n

III. RESULTS AND DISCUSSION

The proposed model is compared with the three methods of Naive Bayes [29], decision tree [30] and nearest neighbour. The relationship between actual classes and predicted classes can be calculated using the Confusion matrix. In Fig6, the required parameters of the Confusion matrix are indicated. At each stage of the implementation of the PSO algorithm, the accuracy of predicting the MLP neural network is increased. In Fig 4, the error percent has been shown in 40 stages for predicting the disease in the proposed algorithm. As seen, the accuracy of predicting breast cancer is increased in each stage.

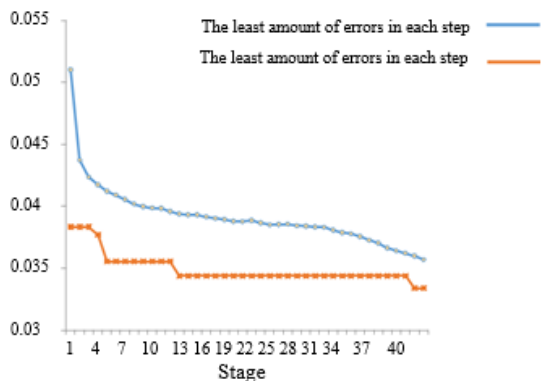

Fig. 4 Error Percent for the prediction of breast cancer in the proposed model

Fig6 illustrates the chart of the results of different methods' diagnosis with the criterion of accuracy. As seen, the proposed model has more accuracy than other methods. Also, the comparison of the results of predicting the disease with the criteria of sensitivity and specificity have been shown in Tables 3 and 4, respectively. Tables 5 and 6 have compared the results of the methods with the Precision and F-Measure criteria, respectively. The comparison results indicate the superiority of the proposed model's performance. In table 7, the proposed method has been compared with other methods by the criteria of F-Measure, Precision, Sensitivity, and Specificity. Table values indicate a better performance of the proposed method.

In this study, a collection of less famous and effective patterns in the incidence of breast cancer has been processed on the basis of a local database. Designing and completing questionnaires, recording clinical symptoms,

and laboratory results in the used datasets have been compiled by the authors of the paper in super-speciality Mortaz hospital, Yazd. Research on breast cancer prediction has some limitations, including the small number of patients for creating the model, missing data and incomplete variables. In this study, the acceptable number of patients with appropriate variables and the least amount of missing data have been used. The present study predicts breast cancer using patients' clinical and laboratory features and through genetic algorithms and data analysis. The proposed model of the study includes the normalization of features, the selection of features, weighting to features, and the introduction of a method for predicting breast cancer through weighted features.

Mass features, tumour size, family history, the number of changes in the image of the previous mammography compared with the current image of the patient had the highest efficacy in the categorization of the proposed model. Also, the features of the type of delivery, breast pain and age of the first abasement had the least effect on categorization. The variables of the type of the used edible oil, fabric material of the bra and use of armpit's spray had no effect on the diagnosis and prediction of malignancy of breast cancer. In this study, in addition to identifying the most important features, we achieved a better performance in terms of accuracy, sensitivity and specificity indicators through the selection of features based on the genetic algorithm.

Aruna et al. predicted breast cancer using observer classifiers such as Naive Bayes and Decision Tree on the datasets of the WBCD database. Based on the criteria of Accuracy, Sensitivity, Specificity, Precision, Recall and F-Measure in the simulation results, the proposed model has better results than this paper [31]. Land and Warhegen used the support vector machine on the breast cancer datasets for prediction [32]. The results of the experiments showed that The support vector machine has an accuracy of 96.7%. Kian et al., by using the RBF and MLP methods for predicting breast cancer, reached the accuracy of 96.18% and 95.74%, respectively [30]. Charasia et al. achieved an accuracy of 96.4% using the SVM method in [34]. Sarvestani et al. predicted malignancy of breast cancer by comparing the mean of squared error in multi-layer, competitive, and radius-based neural networks that the best accuracy was for the radius-based neural network [35]. Lavania et al. obtained an accuracy of 94.84% through the data of the WBCD database and decision tree with a two-stage categorization [36].

Tolouei et al. [37] provided the prediction of relapse of breast cancer using three data analysis techniques. The performed studies show that the accuracy of the three data analysis algorithms, i.e. decision tree, ANN and SVM, was 0.936, 0.494, and 0.947, respectively. Kiani et al., in the developed model [38], had a specificity and sensitivity of 65% and 96%, respectively. In the study reviewing the past, they were used 809 patients with breast cancer and 89 features of each patient. Atashi et al. [39] discovered 100

associative relationships with reliability coefficients above 90%. 10 relationships of the whole were reported as being significant. Kavrasia et al. [40] used a decision tree to predict breast cancer with an accuracy of 74%. The accuracy of 87% in the diagnosis of breast cancer using the C4.5 tree was the result of the work of Soria et al. [41].

Salaama et al. used a fuzzy-neural network approach to predict breast cancer. The prediction accuracy of this method was 95.06% [42]. While the proposed model with an accuracy of 96.6%, the sensitivity of 96.8% and specificity of 97.5% has a better performance in the diagnosis of breast cancer than the methods of Naive Bayes, decision tree, and the nearest neighbour.

In the proposed method, the purpose was to design and evaluate a medical assistant model for the determination of breast cancer malignancy using the PSO algorithm to increase the accuracy of the neural network. The designed medical assistant model in this research has been successful in the diagnosis of malignancy and has performed the categorization with acceptable accuracy. Experiments and simulations showed that the medical assistant system introduced in this study reached the accuracy of 96.6% for the data set of local patients with breast cancer in the Mortaz Hospital of Yazd, which was higher than similar research on different datasets.

IV. CONCLUSION

Search in medical databases for knowledge and information to predict, diagnose and decide is of data analysis applications in medicine. Hereditary algorithms such as genetic algorithms can be used to optimize data analysis techniques. The proper prediction and diagnosis of breast cancer increase the chances of successful treatment with the use of artificial intelligence and machine learning.

In the paper for prediction and diagnosis of breast cancer, the PSO algorithm was used to optimize neural network Results, and a new model was proposed. The simulation results show that the proposed model with the accuracy of 0/966 is more accurate than the methods of Naive Bayes, decision tree and the nearest neighbour.
